

CRYPTO FUTURES TRADERS MANUAL

INSERT YOUR LOGO HERE

**Your Complete Guide to
Crypto Futures Trading**

INTRODUCTION

Welcome, and thank you for being part of this community.

This manual is your complete guide to crypto futures trading, built from real experience, real results, and years of disciplined execution. Inside, you'll find everything you need to understand how the trading setups work, how to execute them properly, and how to manage your positions like a professional.

This isn't theory. Every strategy, every system, and every method shared in these pages comes from thousands of trades, constant refinement, and a commitment to consistency. The goal is simple: to give you the tools, the knowledge, and the structure to succeed in the crypto futures game, whether you're just getting started or looking to sharpen your edge.

Trading is more than charts and numbers, it's about mindset, discipline, and emotional control. That's why this manual doesn't just teach you how to place a trade. It teaches you how to think like a trader, manage risk like a professional, and stay consistent when the market tests you.

Everything has been built to make your journey as smooth as possible. The setups are calculated, the signals are delivered, and the systems are automated, your job is to execute, manage, and trust the process.

Let's get to work, and let's start printing.

- 8.2 – Community, Access, and Authenticity**
- 8.3 – Final Words**

GLOSSARY

1. GETTING STARTED

1.0 – Starting with the Basics

Welcome, this manual is your step-by-step guide to understanding what matters in crypto futures and how to execute trade ideas to their full potential. Futures trading is a dynamic arena that demands risk awareness, strategy, management, patience, and, above all, discipline. It will test your emotions, but developing emotional strength is part of becoming a consistently successful trader.

In the pages ahead, we'll walk through the technicals, fundamentals, psychology, and practical execution, clearly and sequentially, so you know exactly how to approach this game and give yourself the best chance to win.

Crypto futures is a diverse playing field. Even when two traders follow the same setup, results can differ, and that's completely normal. Outcomes are shaped by many variables, including exchange conditions and matching engine behaviour, leverage selected, market liquidity and trading volume, position size, risk management and order placement, slippage, fees, and timing.

Because these factors vary from person to person, your numbers may not match mine or anyone else's. Don't stress about that, stay focused on process and execution. With solid discipline and management, your results can be just as good, and sometimes even better.

1.1 – Introduction & Background

Let me share a bit about my background as a trader. I have been active in the crypto space for almost a decade, exploring nearly every corner of the industry, investing, trading, building crypto projects, launching memecoins, creating NFTs, mining, and many other aspects of this ever-evolving ecosystem. I would say I have done it all.

Personally, I invest and hold most of my capital long-term, allowing it to grow and compound over time. Alongside that, I trade crypto futures, which has been my main focus for the past five years. Through experience, discipline, and thousands of trades, I have developed my own strategies, tools, and systems that consistently deliver results. Today, I also collaborate with major brands, helping their communities benefit from the trading methods and frameworks I have built.

I view futures trading as a game, and you should too. That's the mindset that will keep you sharp and consistent. It's a game where you can profit in both directions, when the market moves up, you can go Long, and when it moves down, you can go Short. It's about positioning yourself correctly at the right time and making the right call on price movement.

This "game" allows flexibility, you can adjust your risk, control leverage, and manage positions strategically. Like any game, there are rules, systems, and elements that must be respected if you want to play it well. Always trade with capital you are comfortable losing, stay disciplined, and don't let fear or greed take control.

The truth is, the potential results are incredibly rewarding. I have been dominating the crypto futures space for years, consistently achieving strong results through disciplined execution. I share this not to boast, but to prepare you for the right mindset. If you respect the rules, use proper risk management, follow the setups, take profits, monitor your positions, and trust the process, you will be successful in the long run.

1.2 – Behind the Scenes

Let's get into what happens behind the scenes, so you can fully understand how the setups are created and how everything works in the background.

First of all, I use TradingView for my analysis, all my trading tools and indicators are built on that platform, and, like every professional trader, I do all of my work there. I follow a strategy that has proven its consistency and accuracy year after year, delivering reliable results every time I conduct an analysis.

My trading tools were developed together with my developer, who used my strategy as the foundation to make my workflow more efficient and my analysis even more precise. These tools provide sharper entry confirmations and more accurate target zones than manual analysis alone. The system has been fine-tuned over time to deliver sniper entries and pinpoint take-profit targets on every setup, and this is the reason why I can confidently share a large number of trade signals with around 85–90% accuracy.

Before diving into the charts, I always start with fundamental analysis. I examine what is happening in the world that can influence the markets, from macroeconomic events and financial news to unexpected triggers like political updates or even something as small as a tweet, everything that moves sentiment matters.

By doing this research first, I form a directional bias for the day, the week, the month, the quarter, or even the year. This step is essential, you should always study the fundamentals before jumping into the technicals, because understanding the bigger picture helps you align your trades with the overall market flow.

It's important to note that the crypto market tends to move together, almost everything follows Bitcoin, which holds around 60% of the total market dominance, meaning Bitcoin acts as the main market mover. When it comes to trading, we focus on USDT pairs, and you should always choose futures perpetual contracts, not spot trading. After analyzing Bitcoin, I move on to altcoins, these offer much larger moves and higher profit potential. This is why we trade a mix of Bitcoin, major alts, and smaller alts, but never memecoins.

1.3 – How the Trading Setups Are Made

When the fundamental and technical analysis are complete, it is time to define a high-confidence entry, clear take profit targets, and a protective stop loss. I do this with my trading tools that calculate the exact entry point, the exact take profit levels, and the stop loss level for each specific pair and setup. I complete all required checks and calculations, structure everything so it is a ready-to-execute trade, and then schedule the setup to be posted and activated at exactly the right time.

The market's price action must complete a series of events, in the correct pattern, to confirm and validate the setup before it is pushed live. Setups activate only when the prior series of events are completed and the price action confirms the validity of the plan. Often, I prepare both directions at the same time, one long setup and one short setup, so we can participate whichever way the market decides to move.

Markets run 24/7, and this workflow lets me keep setups ready and validated even while I sleep. I set the direction, I set the rules, and the market gives the green light when everything aligns.

My tools calculate the precise activation price, the take profit ladder, and the stop loss, all tailored to the specific pair, the leverage plan, the day, the cycle, the price action, and the timing. Targets are generated to the tiniest decimal. Leverage is also calculated specifically for the pair, the price action, the trend, the volatility, and the market timing.

Trades are posted only when the market presents the opportunity and I am confident in the setup. If I am not confident, I do not build the setup, and I do not post it. I will never push trades just to post something.

2. USING THE SETUPS

2.0 – How to Use the Setups Effectively

Setups are only delivered when the market presents clear opportunities and when I am confident they are ready to be activated. Usually, trading setups come 2 to 12 times per day, with an average of around 6 setups daily, depending on the market conditions. Since the crypto market moves 24/7, setups can be sent at any time of the day, regardless of time zones.

I categorise trades into three main types:

- Scalps – quick trades with short movements, low margin, and fast execution. Short-term setups that play out within minutes. If not they become as SWING trades.
- Position trades – setups with three fixed take profit targets and a solid risk-to-reward ratio. First targets can be hit within minutes or hours, higher ones can take days or weeks.
- Swings – longer setups that can take days or weeks to fully complete.

For now, we will focus on position and swing trades, as they are the most beginner-friendly type. These setups include three take profit targets: 1st TP ~ 1:2 R:R, 2nd TP ~ 1:1 R:R, 3rd TP ~ 1:3 R:R.

2.1 – Setting Up Your Trading Panel

Go to your futures trading panel and click the three dots in the top right corner, click Preferences, and make sure every setting is enabled, notifications on, order confirmation on. Before you start trading, switch to Hedging Mode.

Hedging mode allows you to open both Long and Short positions on the same pair at the same time, which matters when two valid signals exist in opposite directions. Once these settings are applied, you are ready for execution.

2.2 – Executing the Trading Setup

Here is how a signal will look:

TRADING SIGNAL ALERT

***PAIR: BNB/USDT #1735
MEDIUM RISK***

***TYPE: SWING
SIZE: 1-4%
SIDE: LONG***

***ENTRY: 639.8
SL: 628.24 (-51.42%)***

TAKE PROFIT TARGETS:

***TP1: 644.69 (20.64%)
TP2: 652.2 (52.33%)
TP3: 679.5 (170.4%)***

LEVERAGE: 27x

***TP1: 0.4 R:R
TP2: 1.02 R:R
TP3: 3.31 R:R***

PROTECT YOUR CAPITAL, MANAGE RISK, LETS PRINT!

The Pair is the instrument you will trade. Select the Futures version with "Perp" shown next to it. Set your Margin Mode – Cross Margin shares all available balance across positions, while Isolated Margin limits risk to each individual trade.

2.3 – Understanding the Entry Price

The entry price mentioned in the signal, next to "ENTRY:", is the level we aim to enter at. If you are quick and using a market order, you should catch the entry very close to that price. Only use a market order if the current price is still within plus or minus 0.3 percent of the given number.

As a general rule, if the trade has not yet reached Take Profit 1, you can still enter, preferably with a limit order, waiting for the market to pull back to the entry point. If the market does not pull back and instead hits Take Profit 1, cancel any open limit orders for that setup.

2.4 – Entering with a Limit Order

If the price has already moved past the entry, the better choice is to use a limit order. Place it at the given entry price and wait for the market to return to that level. You get the exact planned entry instead of chasing the price, and you keep your risk to reward ratio aligned with the original setup.

Remember, missing a trade is always better than entering at a bad level. If the market has moved up and down for several hours without reaching any targets, and the price later returns to the entry level, it is better not to enter. Wait for the next setup instead.

2.5 – Quick-Start Execution Checklist

- [1] Open your exchange and search for the correct PAIR (Futures Perp, not Spot).
- [2] Set your MARGIN MODE – Cross or Isolated, based on your preference.
- [3] Set your LEVERAGE to the exact amount shown in the signal.
- [4] Set your POSITION SIZE – between 1% and 4% of your trading account.
- [5] Check the current price – if within 0.3% of entry, use a Market Order.
- [6] If the price has moved, place a LIMIT ORDER at the signal's entry price.
- [7] Click LONG (green) or SHORT (red) based on the signal's SIDE.
- [8] Immediately set your STOP LOSS at the SL price from the signal.
- [9] Set your TAKE PROFIT targets – TP1, TP2, TP3 as shown.
- [10] Confirm all orders are active. Step away and trust the process.

Once you have done this 10 or 20 times, the entire process will take you under 60 seconds. The key is repetition and consistency. Do not skip any step, especially the stop loss.

3. CORE TRADING KNOWLEDGE

3.0 – What Is Leverage and How It Works

Leverage allows traders to open larger positions than their actual balance by borrowing funds from the exchange, it is a powerful tool that can multiply both profits and losses.

For example: if you use 10x leverage with 100 dollars, you can open a position worth 1,000 dollars. A 1 percent price increase in your favour gives you a 10 percent profit. A 1 percent price drop against you causes a 10 percent loss, which can lead to liquidation.

The higher the leverage, the smaller the price movement needed to wipe out your margin. In short, leverage amplifies both gains and losses, and your margin mode determines how much of your account is at risk.

3.1 – Market Types and Order Types

Market Order – Executes immediately at the current market price. Best for fast entry or exit. The price can slightly differ from what you see, called slippage.

Limit Order – Lets you choose the exact price where you want to buy or sell. The market must reach your set price for the order to execute.

Advanced Limit Order – Gives you extra control options: Post Only, Fill or Kill, and Immediate or Cancel.

Trigger Order (Stop Order) – Activates only when the market reaches a certain trigger price. Used for stop loss protection and stop entries. For our setups, we focus only on Market and Limit orders.

3.2 – Executing the Setups Correctly

For the setups provided, we will be using market orders. This allows us to enter the trade at the exact market price and react quickly when the signal is triggered. Speed matters – every second can influence your entry and profit potential.

Try to place the trade immediately when you receive the signal. If you are late by around five minutes, check the chart to see whether the entry level is still valid. Be fast, focused, and precise.

3.3 – Long and Short Positions

What Is a Long Position – A long position means you are buying an asset because you expect its price to increase. You profit when the market goes up. Buy low, sell high.

What Is a Short Position – A short position is the opposite, you are selling first because you expect the price to fall. You profit when the market goes down. Sell high, buy low.

With leverage, both long and short trades are amplified. In short: LONG = buy, price up equals profit. SHORT = sell, price down equals profit. Both can win, as long as you trade in the right direction.

3.4 – Positions and Open Orders

A position means you are currently in a trade – the order has been executed, and your capital is actively exposed to market movement. An open order means you have set instructions for a trade, but it has not yet been executed.

Think of it like booking a flight. Open Order = you booked the ticket, but you have not departed yet. Open Position = you are already on the plane, in motion toward your destination.

3.5 – Understanding Your Trading Panel

- **Trading Pair** – Shows which pair you are trading (e.g. BTC/USDT Perp).
- **Buy or Sell Direction** – Whether your position is Long or Short.
- **Margin Mode and Leverage** – Cross or Isolated, plus leverage multiplier.
- **PnL (Profit and Loss)** – Your current profit or loss in real time.
- **Entry Price** – The price level where your position opened.
- **Mark Price** – The current live market price.
- **Liquidation Price** – The price at which your position will be automatically closed.
- **Margin Ratio** – How close your position is to being liquidated (100% = closed).

Always pay close attention to four main numbers: your Entry Price, Mark Price, Liquidation Price, and PnL. These together tell you exactly how your position is performing.

3.6 – Funding Rates Explained

When you trade perpetual futures contracts, there is no expiry date, which means the exchange needs a mechanism to keep the futures price aligned with the actual spot price. This mechanism is called the funding rate.

The funding rate is a small fee exchanged between long and short traders at regular intervals, usually every 8 hours. If the funding rate is positive, longs pay shorts. If negative, shorts pay longs.

Why does this matter to you? If you hold a position for several hours or days, the funding rate can add small costs or small earnings to your trade. During extreme market conditions, funding rates can spike significantly, eating into profits over time.

How to handle it: Check the funding rate on your exchange before entering a trade, especially for positions you plan to hold for days. Most exchanges display the current funding rate and the countdown to the next payment right on the trading screen. For our setups, the impact is usually small because we aim for relatively fast exits, but it is good to be aware of on swing trades.

4. RISK MANAGEMENT

4.0 – Risk Management

This is the most important part of trading. The recommended position size is between 1 and 4 percent of your trading account per trade. This ensures no single position puts your capital in danger.

If you prefer slightly higher risk, you can go up to 5 percent, but never exceed that. This range is the foundation of long-term consistency and compounding growth. Without proper risk management, no strategy will survive.

For example, if you have 1,000 dollars in your trading account, proper risk management means placing 10 to 40 dollars per trade. Leverage multiplies your market exposure, allowing you to control a larger position while keeping risk limited.

Stick to the plan, apply consistent risk management, and never treat trading like gambling.

4.1 – Understanding Risk Levels

Every trading signal includes a Risk Level indicator. This tells you how much you could potentially lose on that specific trade if the stop loss is hit, calculated from the entry to the stop loss combined with the leverage used.

LOW RISK – Possible loss up to a maximum of -50%. These are the safest setups. Ideal for beginners or conservative days. Use your full 1–4% position size range.

MEDIUM RISK – Possible loss from -50% to -100%. Moderate exposure – the stop loss is slightly further or the leverage is higher. Consider using 1–2% position size, especially in choppy conditions.

HIGH RISK – Possible loss of -100% or more. Higher leverage or wider stop loss distance. If the trade hits SL, you could lose your entire allocated margin or more on cross margin. Stick to 1–2% maximum.

The risk level is your guide, but your position sizing is your real protection. A high risk trade with a small position can be perfectly safe. A low risk trade with an oversized position can still hurt you. Always match your position size to the risk level.

4.2 – Stop Loss and How to Set It

A stop loss is not your enemy, it is your protection. It automatically closes your position when the price moves against you, preventing losses from growing beyond what you can afford.

Why Stop Loss Is Essential:

1. Prevents emotional decisions – no waiting and hoping for a reversal.
2. Controls risk per trade – you know exactly how much you can lose.
3. Protects capital during volatility – sudden moves won't wipe your account.
4. Keeps you in the game – you stay ready for the next opportunity.

A stop loss should never be random. For a long trade, set it below a strong support zone. For a short trade, set it above a strong resistance zone. Go to your Positions tab, click on TP/SL, enter the SL price, use Market order type, and press Confirm.

4.3 – Do Not Move Your Stop Loss

A common beginner mistake is to move the stop loss further away when the market moves against them. This increases risk and destroys discipline. Set your stop loss before entering, based on logic and structure, and once the trade is live, never move it backward. You can move it forward later to lock in profit, but never to increase risk.

A stop loss is not a sign of failure, it is your defence line. Trading without a stop loss is like leaving your house open in a storm – you might be fine once or twice, but eventually, you will lose everything.

4.4 – When NOT to Trade

Knowing when to stay out of the market is just as important as knowing when to enter. Not every moment is a trading opportunity. Here are the situations where you should step back:

- During major news events – When high-impact announcements or unexpected geopolitical events are about to drop, the market can spike violently in both directions. These moves are unpredictable and can trigger your stop loss instantly. Stay out or reduce position size significantly.
- During heavy consolidation – When the market is moving sideways in a tight range with no clear momentum, setups become less reliable. Price chops back and forth, hitting stops on both sides. Wait for the breakout, then act.
- On low-volume weekends – Weekends often have lower volume and liquidity, meaning wider spreads, more slippage, and increased risk of manipulation through sudden wicks. Be extra cautious with position sizing.
- When you are emotional, tired, or distracted – Trading requires focus and clarity. If you've just taken a big loss and feel angry, if you're exhausted, or if you're distracted, step away. Emotional trading leads to impulsive decisions and revenge trades.
- After a losing streak – If you have had several consecutive stop losses, take a break. Review what happened, reset your mindset, and come back fresh. Do not try to "win it back" immediately.

The market will always be there tomorrow. There is no rush. Protecting your capital by not trading is still a winning move.

4.5 – Expectation Management

Before you take your first trade, you need to understand something fundamental: not every week will be profitable, not every setup will win, and not every month will be easy. This is normal, and it is the reality of every single trader in the world, no matter how experienced.

Some weeks, the market will be on fire – clean trends, strong momentum, and nearly every trade hitting multiple take profit targets. You will feel unstoppable. Other weeks, the market will chop sideways, trigger stop losses, reverse directions repeatedly, and test your patience to the limit. You will feel like nothing works.

Both scenarios are part of the game. The traders who survive and thrive are the ones who understand this from day one. They do not get too excited during winning streaks, and they do not panic during losing streaks. They stay the course, trust the process, and know that over time, the system delivers.

Here is what realistic expectations look like: Out of every 10 trades, roughly 1 to 2 may hit stop loss, 5 to 6 will reach TP1, 3 to 4 will reach TP2, and 2 to 3 will reach TP3. These are averages – some periods will be better, some worse. But if you follow the plan with consistent risk management, the math works in your favour over time.

The biggest danger is not a losing trade – it is your reaction to a losing trade. If one stop loss makes you abandon the system, increase your risk, or start trading randomly, you have let a single result override a proven process. Do not give one trade that much power over your journey.

Set your expectations early, stay grounded, and play the long game. Consistency beats perfection every single time.

5. TRADING PSYCHOLOGY

5.0 – Trading Psychology and Emotional Management

Trading is 20 percent setup and 80 percent emotional control.

- **Discipline Over Emotion** – Once the trade is placed, trust it. Every setup is calculated and structured. Discipline means following the plan even when your emotions tell you not to.
- **Risk Small Enough to Stay Calm** – If you feel nervous or anxious, your position size is too large. If a stop loss hits and you feel fine, you are trading correctly.
- **Losses Are Normal** – Even the best traders lose trades. One loss means nothing in the bigger picture if your system is profitable overall.
- **Don't Overreact or Chase** – After a loss, don't try to win it back immediately. After a win, don't feel unstoppable. Keep your risk consistent.
- **Patience Wins** – Markets do not always move fast. If your stop loss is in place and your risk is controlled, relax and let the trade work.

5.1 – The Trading Game Mindset

Trading is a game of probabilities, not emotions. Think of it like a skill-based game where your goal is to predict whether the price will go up or down. At the end of the day, you are pressing buttons on a screen. Do not attach emotions or personal value to the outcome.

The charts are your map. Signals are like guidance from an experienced player. Take profits are your checkpoints – moments when you secure progress. Stop loss is a correction point, showing where you adjust and move on.

When you treat trading as a skill game instead of a survival test, your emotions calm down. You stop forcing trades, you stop panicking, and you start enjoying the process. The market does not know your name. Your job is to play smart, stay patient, and protect your capital.

The Boxing Analogy

Think of trading like a boxing match. Every good boxer knows that defence wins fights, not just offence. Here is how the analogy works:

- Your guard is your risk management – it is always up, always protecting you. Without your guard, one punch can knock you out. Without risk management, one bad trade can wipe your account.
- Your jabs are your small, consistent trades – they score points, keep pressure on the opponent, and set up bigger opportunities. These are your TP1 hits, your steady gains, the foundation of your success.
- Your knockout punch is the big trend move – when the market gives a clean, powerful trend and your trade rides it all the way to TP3 or beyond. These moments are rare but incredibly rewarding, and they only happen because you stayed in the ring long enough by protecting yourself with your guard and scoring with your jabs.

A boxer who swings wildly without a guard gets knocked out. A trader who takes oversized positions without risk management gets liquidated. A boxer who only defends and never throws punches cannot win. A trader who is too afraid to take setups cannot make money. The balance between offence and defence – between taking calculated trades and protecting your capital – is what makes a champion.

5.2 – Common Mistakes to Avoid

After working with thousands of traders, the same mistakes keep repeating. Learn from other people's errors – it is the fastest way to improve:

- Entering late and chasing price – When the price has already moved significantly past the entry, some traders jump in anyway. This ruins your risk-to-reward ratio. Use a limit order at the original entry or wait for the next setup.
- Using too large a position size – The number one account killer. Traders who risk 10–50% on a single trade are gambling, not trading. One or two stop losses and the account is destroyed. Stick to 1–4%.
- Forgetting to set a stop loss – Some traders enter and plan to set the SL later, then forget. The market can move violently in seconds. Always set your stop loss immediately.
- Closing too early out of fear – The trade dips slightly into the red, panic sets in, you close at a small loss – only to watch it hit all three targets minutes later. Trust the setup.
- Moving the stop loss backward – Instead of accepting the loss, you move the SL further away. This removes your protection and can lead to catastrophic losses.
- Revenge trading after a loss – You take a stop loss and immediately open another trade, often bigger, trying to recover. This emotional reaction almost always leads to a spiral of destruction.
- Trading during choppy markets without adjusting – When the market has no clear direction, reduce your position size to 1–2% and be more selective.

- 
- Skipping trades after a loss – After getting stopped out, some traders skip the next few signals. Often, those skipped trades hit all three targets. The system works across many trades – skipping breaks the edge.
 - Over-managing positions – Constantly checking your phone, adjusting targets, closing and re-entering. Set your SL and TP, then let the trade work.

Recognise these patterns in yourself early. The moment you catch yourself doing any of the above, stop, take a breath, and return to the plan.

5.3 – Survive the Chop, Win the Trend

This is one of the most important principles in trading, and it should become your core philosophy: "Survive the chop, win the trend."

Here is the reality that most traders do not understand: the majority of your damage happens during choppy, sideways markets, and the majority of your profits come during trending markets. If you can survive the chop without blowing up your account, the trends will more than make up for any small losses you took along the way.

During choppy markets, price moves sideways in tight ranges, triggering stop losses on both sides, faking breakouts, and punishing traders who force entries. These are the times when discipline matters most. Reduce your position size, be more selective about which setups you take, and accept that not every day is a profit day.

During trending markets, everything changes. Clean moves, strong momentum, and setups that hit TP1, TP2, TP3 with precision. This is where the real money is made. But you can only capitalise on trends if you still have capital left from the choppy periods.

Think of it this way: choppy markets are the entrance fee to trending markets. You pay a small cost in stop losses and patience during the chop, and you collect a large reward when the trend arrives. The traders who survive the chop with their capital intact are the ones who win big during trends. The traders who over-trade and over-size during chop arrive at the trend with an empty account.

Survival first, profit second. Protect your capital during difficult periods, stay disciplined, stay patient, and when the market finally gives you a clear direction – that is when you strike with confidence.

5.4 – *Theory vs Real Market*

There is a significant gap between how trading looks in theory and how it feels in real time, and you need to be prepared for it.

In theory, charts look clean. Support and resistance levels are obvious. Patterns are textbook-perfect. Entries and exits seem simple. When you look at historical charts, it is easy to say "I would have bought here and sold there." Everything makes sense in hindsight.

In reality, live trading is messy. The market moves fast, candles form differently than expected, levels get swept before reversing, and your emotions are screaming at you to do something – anything – while the logical part of your brain tells you to wait.

Here is what you should expect in live trading that theory does not fully prepare you for:

- **Slippage** – Your entry or exit price may differ slightly from what you see on screen, especially during fast moves or low liquidity.
- **Speed** – The market can move from entry to TP1 in seconds, or it can sit at your entry for hours doing nothing. Both are normal.
- **Volatility** – Price can swing aggressively against you before ultimately moving in the right direction. This is called a "shakeout" and it is designed to stop out weak hands.
- **Emotions** – No amount of theory prepares you for the feeling of watching your money go red. The only way to build emotional resilience is through experience and proper position sizing.
- **Partial fills and missed entries** – Not every order gets filled. Some targets are hit too fast for you to react. Some trades are missed entirely. This is part of trading in fast-moving markets.

The solution is not to avoid live trading – it is to enter it with realistic expectations. Start small, learn through experience, and understand that the gap between theory and reality closes with time, discipline, and repetition.

5.5 – *The Professional Trader Mindset*

"I give you the fishing rod – you must learn how to fish."

This is the most important mindset shift you can make. The setups, the signals, the tools – they are all resources designed to give you a massive head start. But they are not a replacement for developing your own skills, your own understanding, and your own trading instincts over time.

Right now, your job is to follow the system, execute the setups correctly, and manage your risk. That is stage one. But as you spend more time in the market, you will start to notice things – how price reacts at certain levels, what time of day the market tends to move, which pairs behave differently, how your emotions shift during winning and losing streaks.

These observations are the beginning of your own trading education. Over time, you will develop your own sense for the market. You will start to understand why a setup works, not just that it works. You will begin to read charts with more confidence and make more informed decisions about how to manage your positions.

The goal is not to follow signals forever. The goal is to use them as a foundation while you build your own system, your own strategy, and your own trading identity. The best traders I know all started by learning from someone else, and then evolved into independent, self-sufficient traders.

Do not follow blindly. Understand what you are trading and why. Ask questions. Study the market. Learn from every win and every loss. The signals give you an edge today – but your own growth as a trader is what will give you an edge for life.

6. TAKING PROFITS

6.0 – Take Profit Targets

Now comes the fun part, the reason we trade in the first place – to take profits, to make money, to pull money out of the market and bring it home. This is the reward for your execution, discipline, risk management, patience, and emotional control.

A Take Profit (TP) is a pre-set price level where your position automatically closes and secures your profit. Each signal includes several levels: TP1, TP2, TP3. Multiple Take Profit levels allow us to manage both profit and risk strategically.

Think of Take Profits as checkpoints in the trading game. Each one you hit means progress. This is how we trade with discipline, secure our results, and build steady, long-term profitability.

6.1 – Taking Profits and Understanding Flexibility

You can take profits whenever you want. You have complete control over your trades. However, the take profit levels are not random – they are calculated price points where the market is statistically most likely to move. Trust the setup and let it play out.

Not every setup will reach all take profit levels. Not every trade will hit a take profit at all – that's part of trading. Based on years of performance, the system's win rate consistently averages between 70 and 85 percent monthly.

6.2 – Full Take Profits

Closing the full position at a chosen take profit is the simplest approach. If you pick TP1 as your target, it will be hit roughly eighty-five percent of the time. The trade-off is that you may miss larger gains from higher targets. The higher the target, the higher the risk and the higher the potential reward.

6.3 – Going Risk-Free After TP1 (suggested, but not mandatory)

Once TP1 is reached, the trade is proving itself. The objective now is to eliminate downside risk by moving the stop loss to the entry price. This means no matter what happens next, this trade cannot turn into a net loss.

When TP1 hits: close 25 to 30 percent of the position, then move the stop loss from the original level to your entry price. From this point, you are risk-free on the remainder.

Upsides You lock in a risk-free trade. Whatever happens after TP1 you cannot lose on that position. Protects your capital during pullbacks and gives you peace of mind to hold toward TP2 and TP3 without stress.

Downsides The market does not always move in a straight line. Normal pullbacks after TP1 can wick back to your entry, stop you out at break even, and then continue to TP2 and TP3 without you. You protect yourself but sometimes sacrifice the bigger move.

The bottom line, it is a personal choice based on your risk tolerance and strategy. There is no right or wrong answer. TP1 only players move to BE every time. TP3 hunters sometimes give it more room. Know your strategy and stick to it.

6.4 – The Balanced Hybrid Strategy

This approach uses partial profit taking at TP1 and TP2, keeps a smaller portion aiming for TP3, and adjusts the stop loss twice. It balances protection and opportunity.

Core Rules:

1. At TP1 – Close 10% of the position. Set stop loss to entry. Lock in a small gain, remove downside risk.
2. At TP2 – Close 70% of the original position. Secure the bulk of profits.
3. For TP3 – Let the remaining 20% run. If price reaches TP3, the position closes at target. If it reverses, the stop at BE exits the remainder at that level.

With correct execution, this model targets about 25 percent net per trade on average. Use this as your default play while you build skill and confidence.

6.5 – Partial Profit-Taking

Instead of closing the entire position at a single level, we use a ladder of Take Profit targets. Each target is a point where you can secure a portion of profit as price moves in your favour.

- Reduces risk – once TP1 is hit and you close a portion, your overall exposure is lower.
- Locks in gains – you secure profit step by step instead of waiting for the final target only.
- Improves psychology – knowing you have already banked something helps you stay calm.
- Lets winners run – you keep part of the position open to capture larger moves.

6.6 – Account Growth and Compounding

One of the most powerful forces in trading is compounding – reinvesting your profits so that your gains generate their own gains. It may seem slow at first, but over time, the effect is dramatic.

Here is a simple example. Starting with \$500 and achieving a consistent 15% net growth per month:

Month | Starting | Growth (15%) | Ending

-----|-----|-----|-----

1		\$500		\$75		\$575
2		\$575		\$86		\$661
3		\$661		\$99		\$760
4		\$760		\$114		\$874
5		\$874		\$131		\$1,005
6		\$1,005		\$151		\$1,156
9		\$1,521		\$228		\$1,749
12		\$2,001		\$300		\$2,301

In 12 months, \$500 can grow to over \$2,300 – more than 4x your starting capital. And this is with conservative 1–4% risk per trade. As your account grows, your position sizes grow proportionally, but your risk percentage stays the same. A 3% trade on \$500 is \$15. On \$2,000 it is \$60. Your behaviour doesn't change – your dollar returns accelerate.

Recalculate your position size regularly based on your current balance, not your starting balance. This is how you let compounding work for you. Compounding rewards patience – the traders who stick to the plan are the ones who build real wealth.

7. ADVANCED CONCEPTS

7.0 – Built-In Helpers for Faster Execution

To make execution easier, systems have been built that let you act quickly and stay informed in real time. You can press on any digit value in the signal, copy it instantly, and paste it into your trading panel. Enter the position first, then add the TP and SL.

You will receive clear messages whenever a take profit target or stop loss is hit, including the pair, which target was reached, the profit or loss, and how long it took. These updates are generated automatically through the tracking pipeline. Each paired with exact TRADE ID, to understand for which exact trade is the update for.

Understanding the Trade Update Messages

Throughout the life of a trade, you will receive different update messages in the channel. Each one means something specific, and understanding them is essential for managing your positions correctly. Here is what each message means and how you should respond:

TRADE IS LIVE

This message confirms that the trade has officially reached the entry level and is now active. The tracker has picked up the entry and the trade is being monitored. Only after this confirmation is the trade considered live and tracked for performance.

If this message does not appear, it means the market moved too fast and the tracker did not activate the trade at the entry level yet. If the price then continues and hits TP1 before the entry is officially triggered, the trade will be registered as canceled – even if the price later goes on to hit TP2 or TP3. The trade will remain recorded as canceled, not as a TP hit.

However, if you personally entered the trade manually before the cancellation message appeared, you may still be in profit and can continue managing your position however you want. The system simply stops tracking it because the official entry was never activated. There will be no further updates on that specific trade from the tracker.

This happens occasionally in fast-moving markets. It does not mean the trade was bad – it means the price moved faster than the tracker could confirm the entry.

TP TARGET HIT

This is the standard take profit update. It tells you which target was reached (TP1, TP2, or TP3), the profit percentage, and how long it took from entry to target. Use this message to confirm your own position status and to execute your management plan – for example, closing a partial position and moving your stop loss to breakeven after TP1.

BREAK EVEN HIT AFTER TP1 (or TP2)

This notification is specifically for traders who followed the suggested trade management by adjusting their stop loss to breakeven (entry price) after TP1 was hit. It means that after the trade reached TP1, the price reversed back to the entry level and closed out those traders at zero profit or loss on the remaining position.

If you moved your SL to breakeven after TP1, this message confirms your trade is now fully closed. You secured your partial profit at TP1, and the remainder closed at breakeven – no loss on the rest.

If you did not adjust your stop loss to breakeven, you are still in the trade. The price can potentially reverse again and go for the higher take profit targets. You remain in the position until either a higher TP is hit or the original stop loss is reached.

TRADE CLOSED OUT AFTER REACHING TP1 (or TP2)

This message means the trade is fully closed and the setup no longer requires any management. It appears when a trade hit TP1 or TP2, then reversed and closed out at the original stop loss level.

This is not registered as a loss, because the trade did reach TP1 or TP2 before reversing. The final outcome depends entirely on what management strategy you used:

- If you took partial profits at TP1 and moved your SL to breakeven, you secured profit on the partial and closed the rest at zero – a winning trade overall.
- If you took partial profits at TP1 but kept your original SL, the remainder closed at the original stop loss level – your net result depends on how much you took at TP1 versus how much was left.
- If you closed your full position at TP1, you already collected your profit and this message does not affect you at all.

This is why trade management matters. The same setup can produce different results for different traders depending on how they managed their position.

CANCEL THIS TRADE

This is a manual update telling you to cancel the trade immediately. The setup is no longer valid – market conditions have changed, the price action broke the setup logic, or something unexpected happened that invalidates the trade. If you have an open limit order waiting to be filled, cancel it. If you have not entered yet, do not enter. If you are already in the trade, follow the specific instructions provided with the cancel message.

CLOSE THIS TRADE AT BREAK EVEN

This is a manual update suggesting you close your position at the current price, which should be near your entry level. It means the setup conditions have changed and it is no longer worth holding the position. By closing at breakeven, you protect your capital and free up margin for the next opportunity. Act on this immediately when you see it.

MANUALLY ADJUST SL TO BE (Breakeven)

This is a manual update suggesting you move your stop loss to your entry price right now, regardless of whether a take profit has been hit yet. This is typically sent when the market is showing signs of potential reversal or when conditions have become uncertain. By moving your SL to breakeven, you eliminate downside risk on the trade while still giving it room to continue toward the targets. Act on this promptly – it is a protective measure.

How to Use These Updates Effectively

These messages are designed to guide and inform you in real time. You do not need to be staring at charts 24/7 – the update system handles the monitoring and notifies you at the right moments.

When you receive an update, check your position, confirm the status matches, and take the appropriate action based on your management strategy. If a TP hit message comes but your exchange has not filled your order yet, take partial profits manually or adjust your stop loss. If a cancel message comes, act immediately.

The automation handles tracking and reporting. Your discipline and decision-making ensure consistent long-term success.

7.1 – Understanding Exchange & Pair Differences

Every exchange operates with its own liquidity, volume, and pricing data. Small price variations between platforms are completely normal. All trade updates in the group are based on BloFin exchange.

Tips To Improve Consistency:

1. Set Take Profits slightly closer (0.1–0.3%) to increase execution chance on your exchange.
2. Watch slippage on low-volume pairs – prefer limit orders during high volatility.
3. Double-check your orders are active and confirmed before stepping away.

Special Pair Behaviour

Not all pairs behave the same way. Some important differences to be aware of:

- Low-liquidity coins can move in jumps rather than smooth price action. Their order books are thinner, which means price can gap past your entry, your stop loss, or your take profit without cleanly filling at the exact level. On these pairs, consider using slightly wider margins on your TP and SL.
- High-cap pairs like BTC and ETH move more smoothly because they have deep liquidity. Fills are more precise, slippage is minimal, and the charts tend to respect technical levels more reliably.
- Volatile altcoins can produce massive percentage moves in short timeframes. This is why we trade them – the profit potential is higher. But it also means stops can be hit faster, and the emotional pressure is greater. Adaptability is key – treat each pair according to its character, not as if they are all the same.

7.2 – Layering and Hedging Explained

Layering – Opening multiple trades on the same asset, at different times or prices, all in the same direction. It lets you build exposure gradually, smooth your average entry, and allows stronger compounding. Treat every signal as its own trade with its own SL and TP.

Hedging – Opening opposite trades on the same pair. Used when the market structure changes temporarily. It neutralises exposure and reduces big equity swings. Treat each trade as separate. Don't close an older position just because a new opposite one appears.

Layering builds stronger exposure when confident in a direction. Hedging protects equity and adds flexibility when uncertain. Follow the structure, keep risk consistent, and let data decide the outcome.

7.3 – What to Do When... (Troubleshooting)

Answers to the most common situations traders face. Bookmark this section.

"What if I accidentally entered the wrong direction?"

Close immediately with a market order. Then re-enter correctly if the entry is still valid. Every second in the wrong direction is unnecessary risk.

"What if I missed a signal by 30+ minutes?"

Check the current price against the entry. If still within 0.3%, use a market order. If it has moved, place a limit order at the original entry. If TP1 has been hit, skip and wait for the next one.

"What if my stop loss didn't trigger?"

This can happen in extreme volatility when prices gap. Close manually with a market order immediately. Always use market stop loss orders, not limit stops.

"What if my exchange doesn't have this pair?"

Simply skip that trade. Do not use an unfamiliar exchange just to catch one trade. There will always be another opportunity.

"What if I'm running low on margin with multiple trades open?"

You have over-allocated. Reduce your next position size or close some positions near breakeven. Never have more than 50% of your account committed across all open trades.

"What if the price gaps past my take profit?"

This works in your favour. Your order will execute at the next available price, which may be even better than your target.

"What if I see conflicting signals on the same pair?"

This is hedging (section 7.2). Both signals are valid for different timeframes. Enter both with their own SL and TP. Your hedge mode should already be enabled.

"What if the market crashes suddenly?"

If your stop losses are set, you are protected. Do not panic-sell positions that haven't hit their stop. Check for channel updates and trust your risk management.

7.4 - Why Your Order Can Fill Even When the Chart Didn't Touch the Price

Sometimes you will notice something that seems confusing at first: your take profit or stop loss order gets filled, but when you look at the chart, it appears that the price never actually reached that level. The candle on the chart does not seem to touch your target, yet your order executed. This is not an error – there is a logical explanation.

Charts display price data based on specific time intervals. If you are looking at a 5-minute candle, that candle only shows the open, high, low, and close of that 5-minute period. But within those 5 minutes, the price may have spiked or dipped to a level that is not clearly visible on the candle's wick, especially if the move happened in a fraction of a second before reversing. The move was real, it happened in the live order book, and your order was filled at that moment – but the chart's visual representation might not capture every single tick.

This is especially common during high-volatility moments, news events, or when large orders are executed in the market. Price can briefly touch a level for just milliseconds – long enough to trigger and fill orders sitting at that price, but so fast that the charting software rounds or smooths the candle in a way that makes it look like the level was never reached.

Additionally, there is a difference between the last traded price, the mark price, and the index price on most exchanges. Your chart might display the mark price, while your order was triggered based on the last traded price, or vice versa. These prices are usually very close to each other, but during fast moves they can briefly diverge by a small amount – enough to fill an order at a level that the chart does not visually show.

Another factor is the bid-ask spread. The price shown on the chart is typically the last traded price, but your sell order (take profit on a long) fills at the bid price, and your buy order (take profit on a short) fills at the ask price. During volatile moments, the spread can widen slightly, meaning your order fills at a price that is a fraction different from what the chart candle displays.

In simple terms: the chart is a simplified visual summary of what happened. The order book is what actually happened. Your order interacts with the live order book, not with the chart. If your order filled, it means the price did reach that level in the real market, even if the chart does not show it perfectly.

This is completely normal across all exchanges and all markets. Do not second-guess a filled order just because the chart looks slightly different. Trust the execution, and focus on managing the trade from that point forward.

When a take profit or stop loss update is shared in the channel, it means the tracker has confirmed that the target was reached and the data has been sent to the database. This is an automated process – nothing is forced or manipulated. The tracker monitors the market, and when the price hits the target level, it registers the fill and generates the update message.

However, it is completely normal for your position on the same exchange to not fill at the exact same moment as the tracker, or in some cases, to not fill at all even though the update says the target was hit. This is not a bug or an error – it is simply how markets work.

Think of it like a farmers' market. Imagine you and another person both want to buy apples at exactly 2 dollars per kilo. A seller arrives with 10 kilos at that price. The person standing closer to the seller buys their 10 kilos first, and by the time you step forward, that seller is done. The price was right, the apples were there, but there were not enough for everyone at that exact moment. You might need to wait a few minutes until another seller shows up with more apples at the same price – or the next batch might cost 2.05 instead of 2.00.

The same thing happens on an exchange. When price reaches your take profit level, there needs to be a buyer or seller on the other side at that exact price and quantity to fill your order. The tracker's position might get filled instantly because it was first in the queue, while your position might fill a few seconds later, or at a slightly different price due to order book depth and execution priority.

This is why you might occasionally see a TP hit message while your own position is still open, or your order fills a moment later at a slightly different level. It can also work in your favour – sometimes your position fills before the tracker registers it.

A few things to keep in mind:

This is standard market behaviour across every exchange in the world, not just crypto. It happens in stocks, forex, commodities – anywhere orders are matched between buyers and sellers.

If a TP update is posted but your order has not filled yet, do not panic. Give it a moment. If the price has moved past your target, you can close manually at the current price, which may be better or slightly worse than the original target.

Slight differences in fill price between you and the tracker are normal and expected. A few cents or fractions of a percent will not meaningfully affect your overall results.

The tracker is a reference point, not an exact mirror of your personal execution. It shows that the target was reached in the market, which confirms the setup worked as intended. Your individual fill depends on your exchange's order book, your position size, and the exact timing of your order.

This is part of real-world trading. Over hundreds of trades, these small differences average out and have minimal impact on your overall performance. Focus on consistent execution and proper management, and the results will follow.

8. COMMUNITY & UPDATES

8.0 – About Me, and You

I trade and work every day, always searching for the best possible setups that both you and I can take to capitalise on. Every signal you receive goes through my personal analysis, my systems, and my tools before it's shared. I'm fully committed to delivering quality setups consistently.

There might be rare occasions when I'm not at the charts, like Christmas, my birthday, or when I'm traveling. On those days, I usually prepare setups beforehand and let automation take over. I'm also building a team of skilled traders so that when the time comes, they can step in and continue.

Even though I have automated systems, the setups still require my analysis and confirmation before they go live. So if there's ever a quiet day, it's not because I've disappeared, but because I'm making sure that every setup shared is precise, confident, and worth your time and capital.

8.1 – Market Updates, Reports & Performance Tracking

I will update you every morning about the previous day's results, events, and overall market behaviour. I'll also share macro updates daily, technical updates, chart insights, and active trade summaries.

To keep everything transparent, I'll release weekly and monthly PNL reports. Your personal result may differ, and that's completely normal depending on many variables.

8.2 – Community, Access, and Authenticity

You now have access to everything – the trading signals, the updates, the analysis, the reports, and most importantly, the community. The community is what gives this real meaning. You are in a good place with people who want the best for you. The owner of this group and I have an official partnership, which allows my work to be shared with you.

We are here to provide the best value, the best trades, the best systems, analysis, support, and guidance, so that you can succeed in crypto futures trading.

Final Words

Use this trader's manual as your guide as you navigate the world of crypto futures trading. Every setup is an opportunity. Every trade you make is a move in this game, and every win, loss, or breakeven is a lesson that shapes you into a more skilled trader.

Manage your risk wisely, control your emotions, trust the setups, act fast but with discipline, stay consistent, and be patient. Success will come. You're surrounded by a great community of members and admins who want to see you win.

This is your big step forward and a strong head start. If I ever develop new tools, systems, or methods that can add value to your trading process, I'll update this manual and make sure you stay informed.

One Final Principle: Consistency Over Perfection

You do not need perfect trades. You do not need to catch every signal, hit every target, or never take a stop loss. What you need is consistent execution – the same risk management, the same discipline, the same process, trade after trade, week after week, month after month.

Perfection is the enemy of progress in trading. The trader who follows the system 90% of the time with proper risk management will always outperform the trader who chases perfection, overthinks every entry, and changes strategy every week. Show up, follow the plan, manage your risk, and let the results compound over time.

The market rewards consistency. Not perfection, not luck, not intelligence – consistency. Be the trader who does the same thing correctly, over and over again, and the results will speak for themselves.

All the best, it's time to print.

GLOSSARY

Breakeven

The point where a trade has zero profit and zero loss. Moving your stop loss to breakeven means the trade can no longer result in a loss.

Cross Margin

A margin mode where all available funds in your futures wallet are shared across all open positions. More flexibility but puts your entire balance at risk.

Entry Price

The price at which your trade is opened. The starting point for calculating profit or loss.

Funding Rate

A periodic fee exchanged between long and short traders on perpetual futures, used to keep futures price aligned with spot price. Usually every 8 hours.

Hedge Mode

An exchange setting allowing you to hold both a long and a short position on the same pair simultaneously.

Isolated Margin

A margin mode where only the amount assigned to a specific trade is used. If liquidated, only that margin is lost.

Leverage

A multiplier allowing you to control a larger position than your actual capital. 10x leverage means \$100 controls a \$1,000 position.

Limit Order

An order to buy or sell at a specific price you choose. Only executes when the market reaches that price.

Liquidation

When the exchange automatically closes your position because your margin can no longer support the loss. Results in total loss of allocated margin.

Long Position

A trade where you buy an asset expecting the price to increase. You profit when price goes up.

Margin

The actual amount of your own capital used to open and maintain a leveraged trade.

Margin Ratio

A percentage showing how close your position is to liquidation. 100% = liquidated.

Mark Price

The fair market price used by exchanges to calculate liquidation levels. Prevents manipulation through sudden spikes.

Market Order

An order that executes immediately at the best available current market price.

Perpetual Contract (Perp)

A futures contract with no expiry date. You can hold indefinitely, subject to funding rate payments.

PnL

Profit and Loss – your current profit or loss on an open position, displayed in real time.

Position Size

The amount of capital allocated to a single trade as a percentage of your total account.

Recommended: 1–4%.

Pullback

A temporary price reversal within a larger trend. Can offer secondary entry opportunities.

R:R (Risk-to-Reward)

The ratio between potential loss and potential profit. 1:3 means you could win 3x what you risk.

Scalp

A very short-term trade capturing small, quick price movements. Usually lasts minutes.

Short Position

A trade where you sell expecting the price to decrease. You profit when price goes down.

Slippage

The difference between expected and actual execution price. Common during high volatility.

Stop Loss (SL)

A pre-set price level that automatically closes your position to limit losses.

Swing Trade

A trade held for days or weeks, capturing larger price movements.

Take Profit (TP)

A pre-set price level that automatically closes your position to lock in profit.

Trailing Stop

A dynamic stop loss that moves automatically in your favour as price moves.

Trigger Order

An order that only activates when the market reaches a specified trigger price.

USDT

Tether – a stablecoin pegged to the US dollar. All trading pairs in our setups are quoted against USDT.

Volatility

The degree of price fluctuation. Higher volatility = bigger, faster price swings.
